

Guide for using REtracker Bliss with nDisplay and Switchboard for ICVFX work in Unreal Engine 5.3.2

by Rune Sörgård

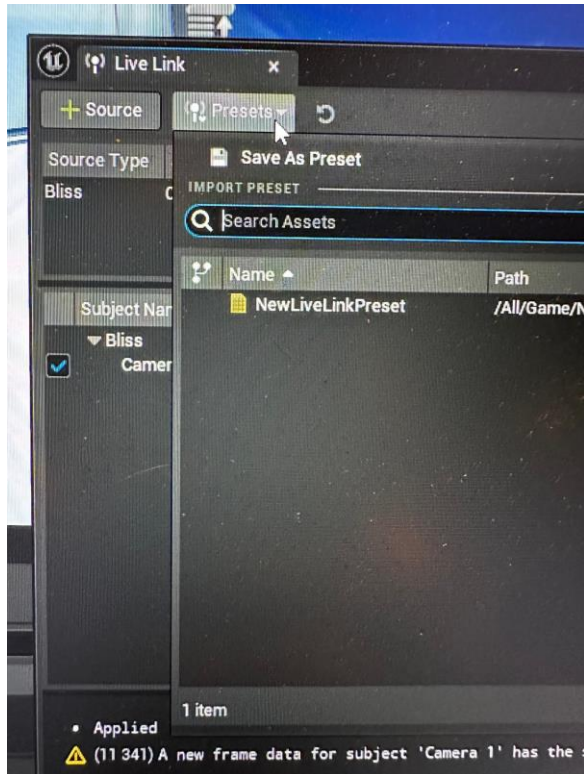

1: set Bliss to IP of machine running Bliss software to xxx.xxx.x.255 (IP of PC that runs Unreal and replace the last digits with 255)

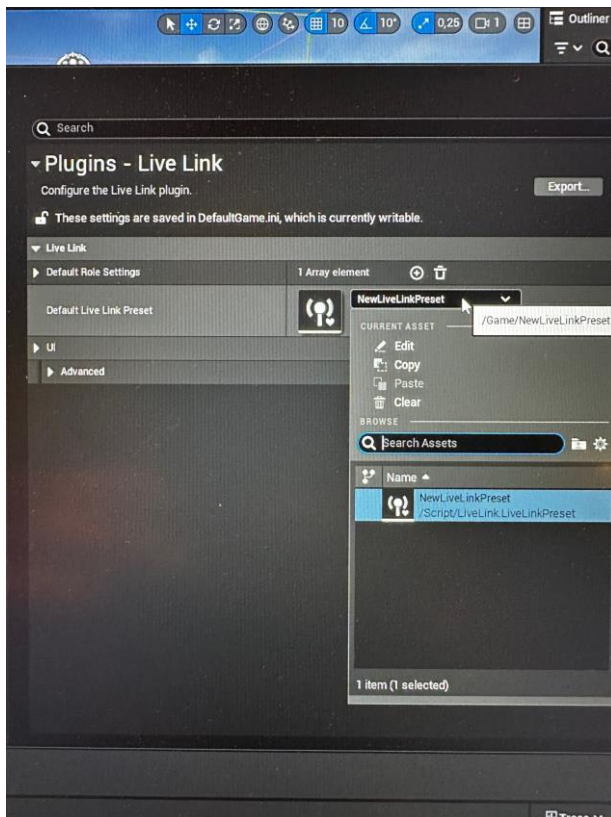

2: Install and enable LiveLinkBliss5.3 In UE project. Open live link tab, add LiveLinkBliss source with IP 0.0.0.0

save as Live Link preset, name as you like.

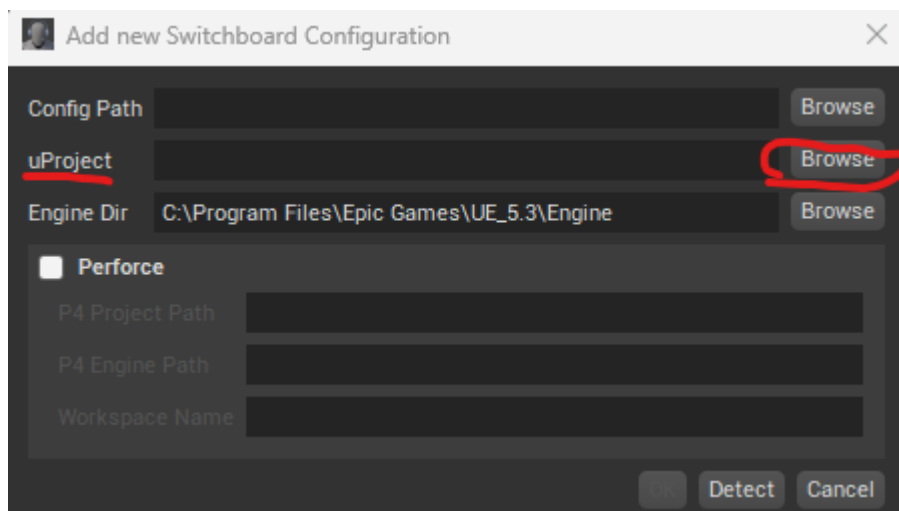

In Projects Settings -> Plugins -> Live Link, choose the newly saved Live Link Preset you created. This will ensure this preset is loaded when project is launched from Switchboard.

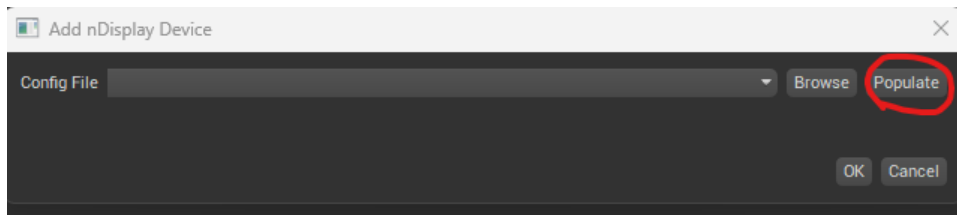

Switchboard: (if using two PC's or more)

The UE project you've created is then chosen as the uprojectpath when creating new Switchboard Config.

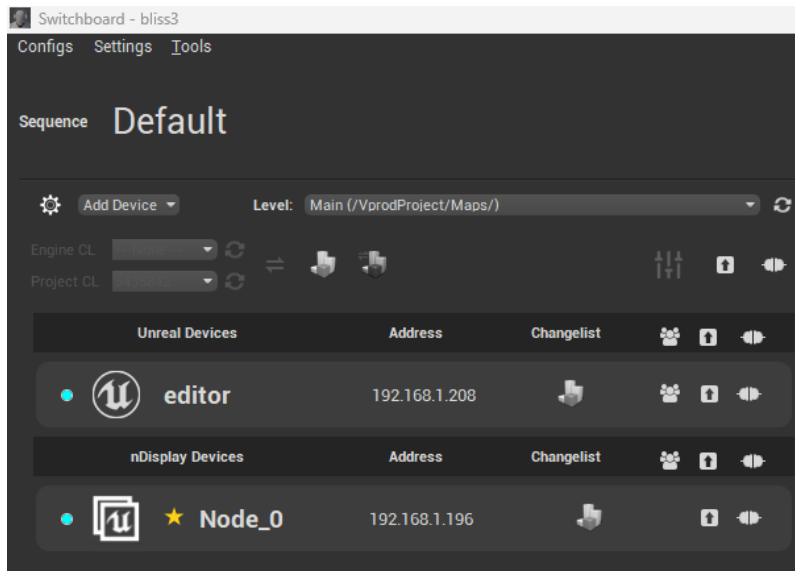

Then you will need to choose your nDisplay device created in your UE project so the correct nDisplay config is loaded (*.ndisplay)

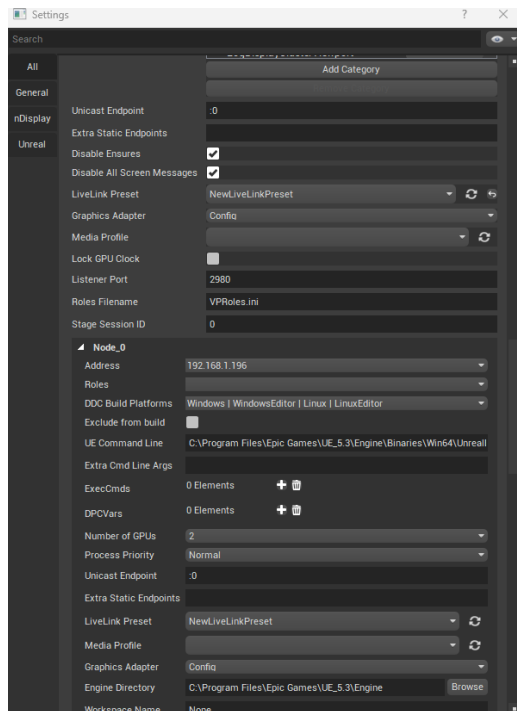

1: Add Unreal Device (Editor) set IP of PC

2: Add nDisplay Device (Render node) set IP of PC

3: Open Switchboard settings

enable live link preset where needed and check that IP addresses are correct for nodes.

I recommend starting Editor first to see that MultiUser starts up correctly and Editor node is added to session, then start render node, and it will connect to session.

Two identical projects needs to be placed in root of PC's to be able to be reached eg C://Unreal Projects/BlissTest. Path must be identical on all PC's to be started from Switchboard.

There are better ways of managing projects, eg. NAS, FreeFileSync, GitHub, Perforce and more options out there.

MultiUser, so you can have Editor node for manipulating your environment and have it update real time in nDisplay is another matter, here are some Unrealdocs for reading:
